THE CALIBRATION OF MILITARY  
CARTOGRAPHIC CAMERAS

by

Robert M. Spriggs

WRIGHT-PATTERSON AIR FORCE BASE, OHIO

15 February 1966

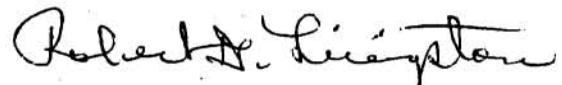

AFLC-WPAFB-MAR 66 500

PREFACE

The files of the GIMRADA Field Office contain calibration certificates for all military cartographic cameras developed by the U. S. Air Force. In this report, the author has extracted pertinent information from these certificates and has presented this information in a form which should be of a considerable value to personnel in map and chart production.

Mr. Robert Spriggs, who authored the report, and Mrs. Jerri Amos, who performed the typing, deserve much credit for the work involved in the extraction of data and in the preparation of the report.

This technical note is one of a series published internally by GIMRADA Field Office and disseminated to support military mapping development by the Department of Defense.

ROBERT G. LIVINGSTON  
Chief, GIMRADA Field Office

## THE CALIBRATION OF MILITARY CARTOGRAPHIC CAMERAS

-----

### I. Introduction:

The accuracy of photogrammetric mapping methods depends in part on the quality of the camera used. For this reason photography intended for photogrammetric mapping must be taken with a camera designed for this purpose.

### II. Mapping Camera Characteristics:

The mapping camera must, (1) have a lens designed with definite distortion characteristics and, (2) be a rigid mechanical structure which holds the lens, fiducial marks and focal plane in a fixed orientation so that dimensional integrity will be maintained. A typical mapping camera (the Type KC-1) is shown in Figures 1 and 2.

### III. Camera Calibration Requirements:

Cameras are calibrated to determine the precise value of the calibrated focal length, the magnitude of the radial and tangential distortion, the position of the fiducial markers and other dimensions. The manufacturer publishes calibration certificates for each camera. Cameras are recalibrated and new certificates issued whenever maintenance is required that will disturb the dimensional relationship of the lens, fiducial markers, focal plane, etc.

### IV. Equivalent Focal Length, Calibrated Focal Length:

The equivalent focal length (EFL) is the distance from the rear node to the focal plane. It is computed by measuring the scale of the image produced by the lens at or near the axis.

The calibrated focal length (CFL) is the numerical value used to determine the scale of the photograph. It is computed from the EFL to obtain minimum distortion or to match the lens distortion to a predetermined curve. An increase in the value of the CFL will make the distortion more negative. For a distortion-free lens the CFL is equal to the EFL.

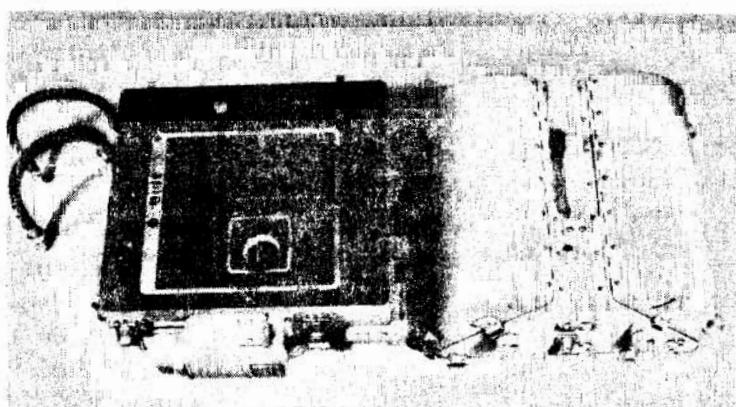

Fig. 2 KC-1 Camera with Film Magazine Removed

## V. Distortion:

Distortion in a lens results in a change in scale over the picture area. Distortion generally is expressed in polar coordinates as radial or tangential distortion.

A. Radial distortion, often referred to as "distortion," is made up of two components, symmetrical and asymmetrical. Symmetrical distortion is a characteristic of the lens design; its effect can be minimized by corrector plates when the negatives are printed or by using cams on the stereoplotter. Asymmetrical distortion (often classified as prism effect) is a property of lens manufacture induced by the decentering of one or more of the lens elements, by irregularities in the surfaces of the lens elements, and by tipping of the focal plane with respect to the lens axis.

B. Tangential distortion is a function of lens manufacture and is caused by the prism effect. The axis of maximum tangential distortion usually will be  $90^{\circ}$  from the axis of maximum asymmetrical radial distortion.

## VI. Camera Calibration Methods and Equipment:

Cameras are calibrated by either of two methods - photographic or visual.

A. The photographic method is the most desired and can be accomplished on a field range or by use of a multicollimator bank.

1. The Field Range Distortion Calibrator (See figure 3) is constructed by setting up targets in the object space in a plane perpendicular to the optical axis of the lens. The targets are placed at selected angles across the entire field of the lens and the angles are determined within 2 seconds of arc. The camera is mounted with the front nodal point placed over the vertex of the range with the center target on the axis of the lens.

2. The Multi-Collimator Bank Distortion Calibrator (See figure 4) is similar in principle to the field range except that collimators are used to image the targets at infinity. The collimators can be positioned to image the targets of both diagonals on one exposure.

3. Exposures are made on test plates with the image of the targets aligned with each diagonal of the camera format. The test plate is processed and the distance between the axial target

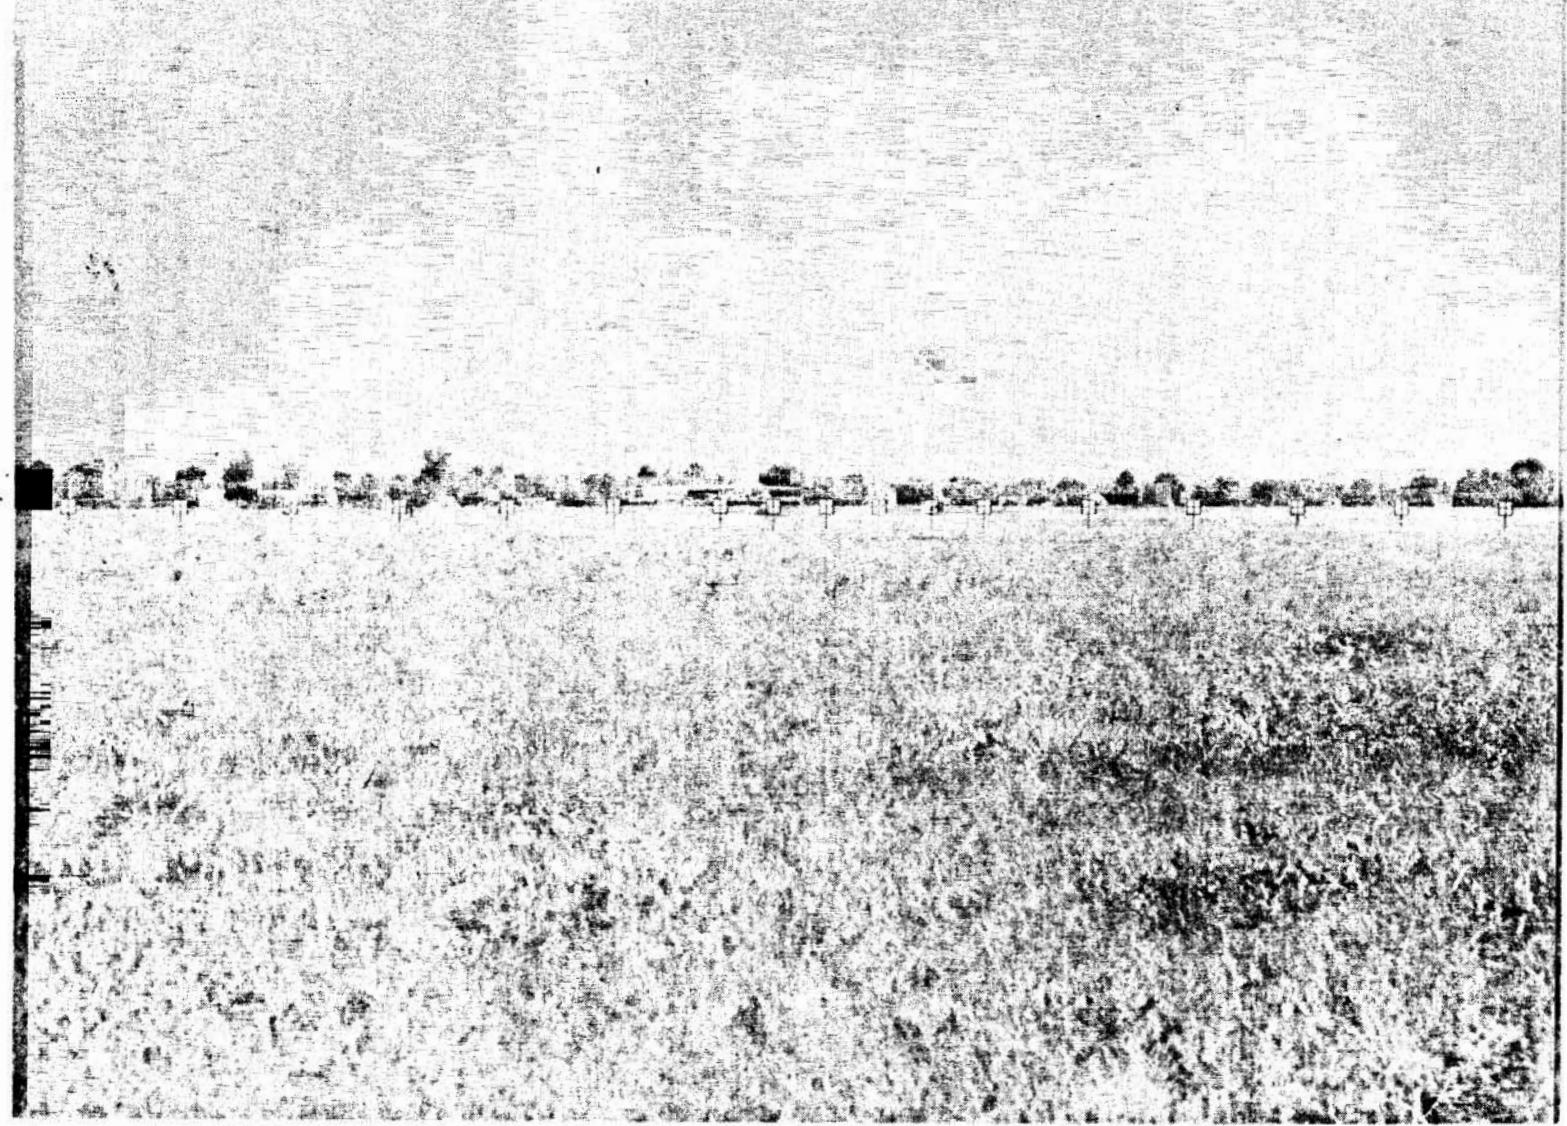

Fig. 3 Field Camera Calibration Range at Wright-Patterson AFB, Ohio.

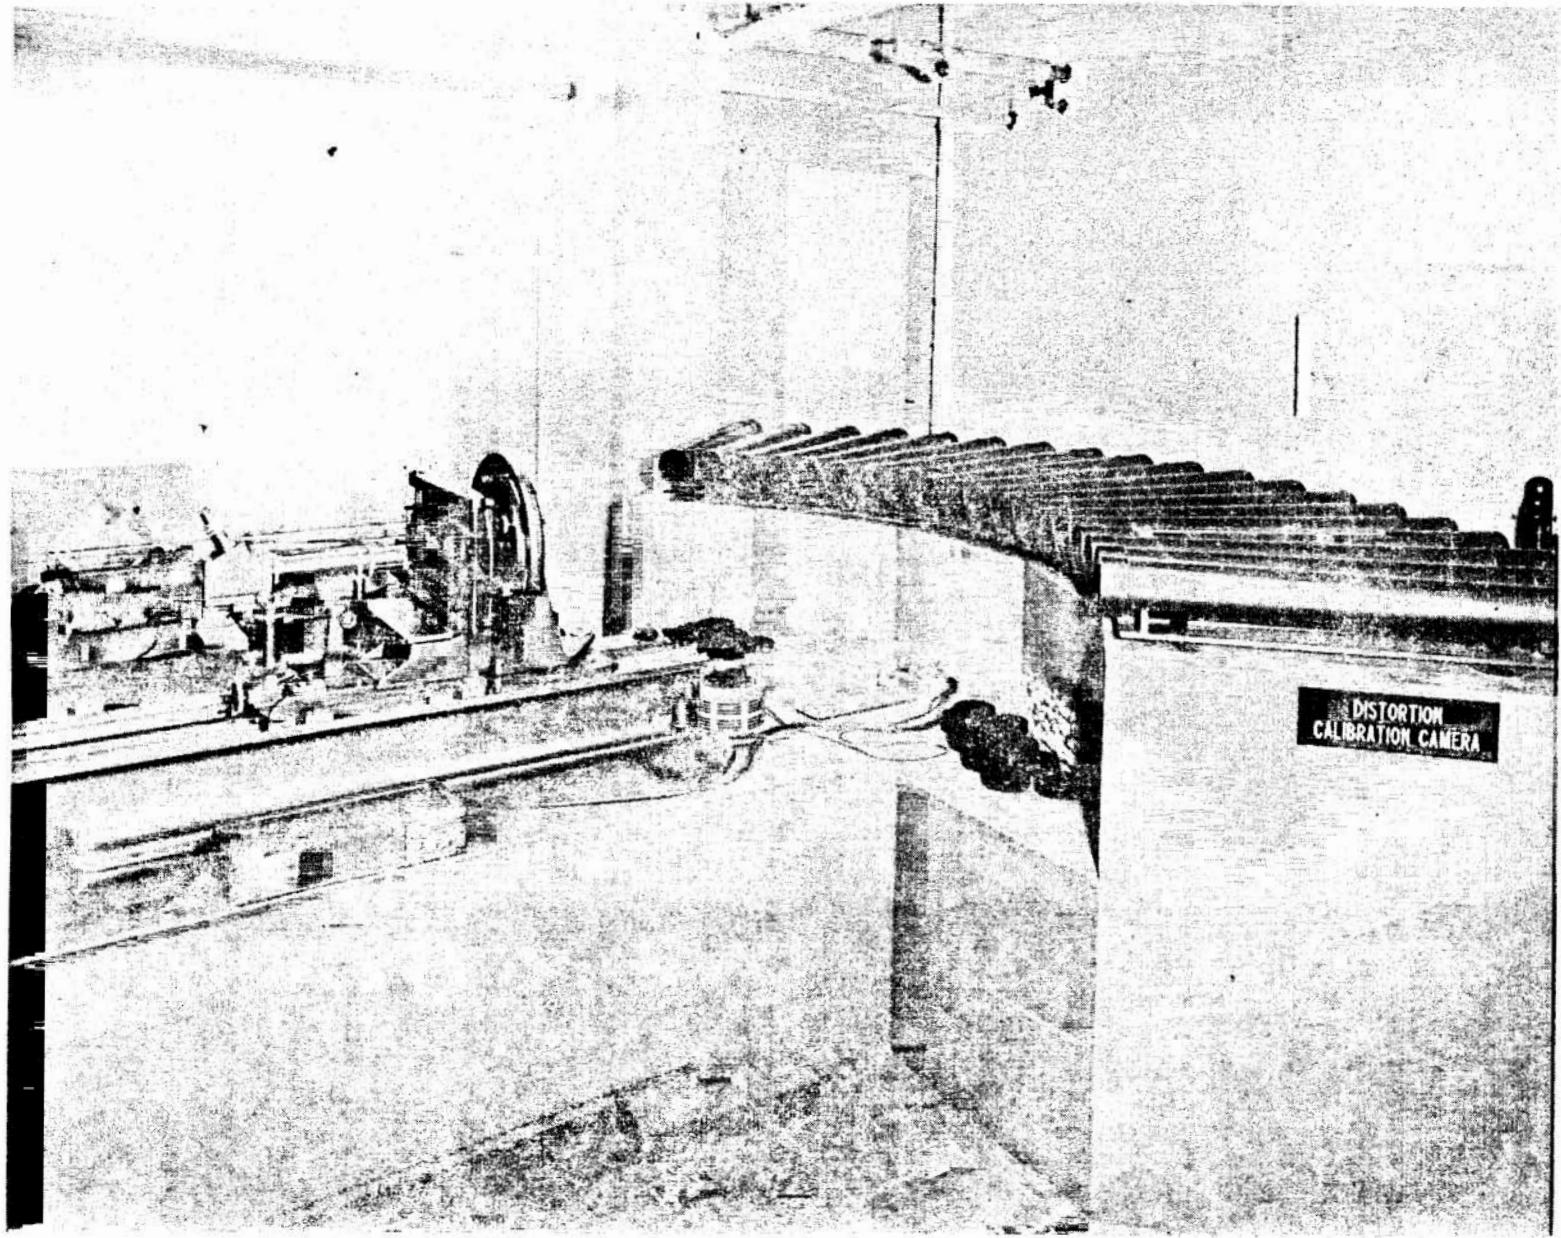

Fig. 4 Multi-Collimator Bank Distortion Calibrator (Perkin-Elmer)

image and the target image at each angle is measured with a comparator. Radial distortion is the difference between the computed distance and the measured distance to each target image. The point of symmetry is determined by making the distortion to the left and right of the axis symmetrical. The calibrated focal length is computed and the distortion is adjusted to the calibrated focal length.

4. The tangential distortion is measured for each diagonal on the test plate.

B. Visual methods may lead to distortions which are different in magnitude than the distortions recorded photographically because of lateral chromatic aberration in the camera lens. The proper light source and/or filters should be selected so that the spectral sensitivity of the eye is matched to that of photographic films.

1. Goniometer method: An accurately calibrated test object on glass is placed in the focal plane and illuminated in a direction toward the lens. The camera is set on the goniometer (See Figure 5) so that the axis about which the angles are measured passes through the center of the entrance pupil of the lens. The telescope of the goniometer is pointed at successive points on the test object and the field angles determined. From the focal length of the lens being tested and the calibration of the test object, the angles subtended by the various points on the test object can be computed. The distortion is computed from the difference in angles on the object side and image side of the lens and converted to the standard form.

C. Some work has been done an stellar calibration of ballistic cameras. The star field is photographed on a glass plate in the focal plane of the camera. The position of each star is measured in x-y coordinates. The true location of the stars are obtained from star tables. The radial and tangential distortion at each star image is determined. The calibrated focal length is computed. It has been suggested that the stellar method of camera calibration be adopted for aircraft mapping cameras.

## VII. Resolution:

The resolving power of a camera lens is its ability to image closely spaced objects so that they are recognizable as individual objects. The resolving power, called resolution, is measured by photographing a test target made up of groups of parallel straight lines and spaces of equal width; it is expressed in lines per millimeter. Radial resolution is measured with the lines parallel to the

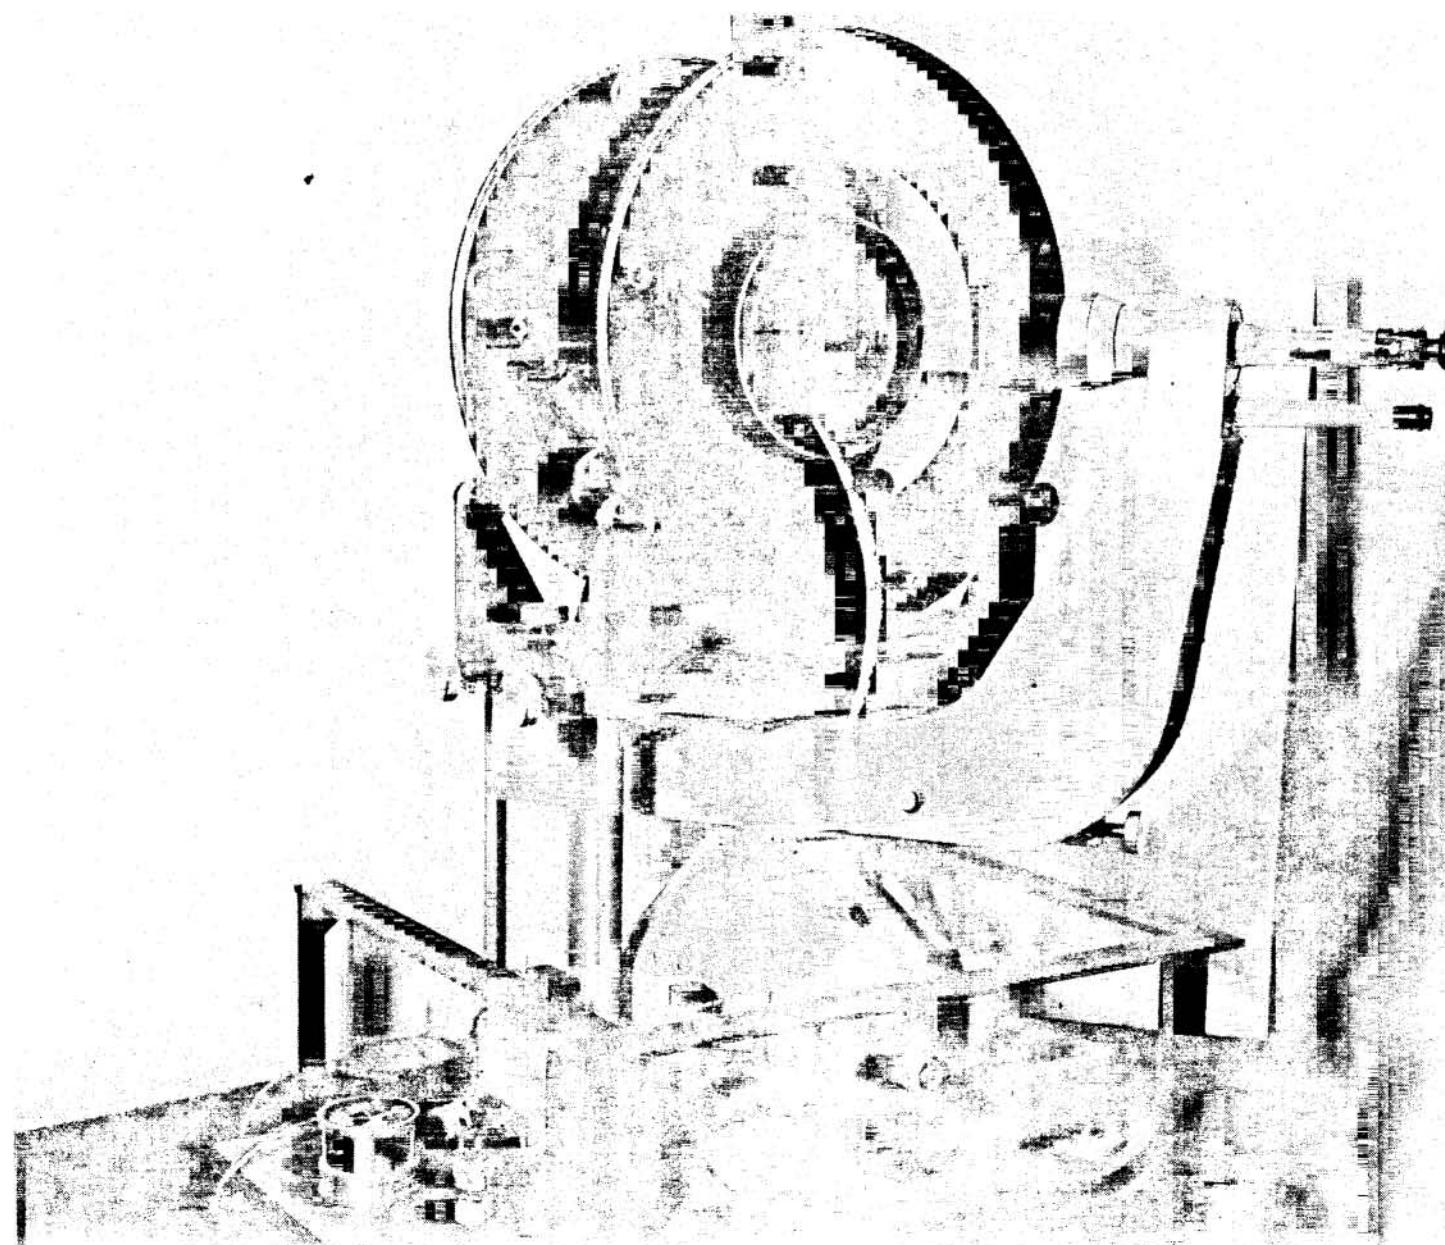

Fig. 5 Wild Type T-4 Bacteriophage

radius drawn from the center of the format and tangential resolution is measured with the lines perpendicular to the radius. A single average value for resolution is determined as the area-weighted average resolution (AWAR) by dividing the format into concentric annular zones. The area of each zone lying within the format is used in determining the weighting ratio. The square root of the product of the radial and tangential resolution is computed for each zone and multiplied by the zone ratio to obtain the zone-weighted resolution. The AWAR is the sum of the zone-weighted resolutions.

#### VIII. Calibration Data:

The calibration data for the mapping cameras, listed in the appendices, was extracted from the camera calibration certificates issued by the manufacturer. Some of the cameras have been overhauled and recalibrated and the data from each calibration certificate is listed.

The probable errors of the calibrated focal lengths are:

T-11	0.100 mm
KC-1	0.100 mm
T-12	0.100 mm
CA-14	0.100 mm
KC-1B	0.025 mm

The probable errors of the distortions are:

T-11	0.020 mm
CA-14	0.020 mm
KC-1	0.010 mm
T-12	0.010 mm
KC-1B	0.005 mm

ADDENDUM NUMBER 1

TO

"THE CALIBRATION OF MILITARY CARTOGRAPHIC CAMERAS"

TECHNICAL NOTE 63-2

1. Additional calibration certificates for cartographic cameras in the USAF inventory have been received by the GIMRADA Field Office. Some of these cameras were developed for research purposes; therefore, Appendix G is added to include cameras which are not made in production quantities. Many of these cameras were developed by modifying KC-1 cameras.

2. The KC-6A camera is designed and produced specifically for the USQ-28 mapping and geodetic subsystems. Two cameras are installed in each system. The cameras have many features that were not found in previous mapping cameras in the Air Force inventory:

- a. Platen reseau, 25 points
- b. Image motion compensation
- c. Verticality readout referenced to the Hipernas II  
Inertial Reference Unit
- d. Synchronous operation of two cameras
- e. Automatic Exposure Control

Present plans are for the purchase of 10 ea. KC-6A cameras and 24 ea. KC-6A magazines. The camera was designed for the USQ-28 system in the RC-135A aircraft and is not readily adaptable to other photographic systems.

3. Changes and additons to Appendices:

a. Appendix A:

Place (1) in front of T-11 cameras with serial numbers 51-211 and 51-212. Add the attached data.

b. Appendix B:

Add the attached data.

c. Appendix D:

Additional information on the KC-1B cameras is attached. The maximum asymmetry between  $0^\circ$  and  $42\frac{1}{2}^\circ$  may be added in the unused column

[Redacted]

[Redacted]

to the right of the page. The maximum radial distortion in the format of each camera is included for your information.

d. Appendices F and G are new additions to the report.

R. M. Spriggs
